Abstract

We examine extended bound states in the dilute limit of the extended Hubbard model with next-nearest-neighbour (nnn) hopping and nnn interaction on the two dimensional square lattice. By the exact solution of a two-body problem we show that d -wave pairing is strongly favored by the nnn hopping. We determine the binding energies, mobilities and dispersion curves across Brillouin zone (B.z.) for bound states of various symmetries. The numerical analysis shows that the deep bound states can exist in the whole B.z. and we have also found $s^* - d$ mixing of the bound states.

I. INTRODUCTION.

The question of the symmetry of the superconducting order parameter arose very soon after the discovery of high temperature superconductivity (HTS). Different symmetries imply superconductivity of considerably different properties and large efforts have been devoted to determining the type of pairing in different materials. Experimental findings have yielded ambiguous results, yet they strongly suggest explanations extending beyond the simplest s -wave picture, possibly d -wave or mixed state in cuprate HTS. Recently, the angle-resolved photoemission spectroscopy and tri-crystal Josephson effect [2] revealed a large d -wave component in the order parameter of cuprate superconductors. Apart from different pairing mechanisms favoring this kind of pairing, this situation may be due to kinetic mechanisms, as suggested by Blaer et al [1]. With inclusion of the nnn hopping, a bound pair formed on adjacent lattice sites can propagate over long distances before decaying. The effective mass of such a pair can become even smaller than the mass of its constituent fermions. The issue of nnn hopping has also important implications for the problem of hole motion in an antiferromagnetic background [3] and for the explanation of the HTS properties [4]– [6].

Exactly solvable model of two fermions on a periodic lattice would give a valuable insight into the problems of both: the role of nnn hopping and the symmetry of the superconducting state.

*karen@delta.amu.edu.pl

†rom@alpha.amu.edu.pl

It is also of importance, as a limiting case for the two relevant models of superconductivity: BCS and preformed pairs scenario.

In this paper we report results of exact calculations of bound states (BS) of fermions on a 2D square lattice including nnn hopping and nnn interactions, using formulation of Ref. [1]. We have evaluated the pair binding energies, pair mobilities and dispersion curves across the Brillouin zone for the extended Hubbard model for different pairing symmetries. We discuss in detail the effect of nnn hopping t_2 and nnn interactions W_2 , on the stability of the shallow BS.

II. FORMALISM

A. The model

The details of the theoretical treatment are given in [1] so we shall give here only the main points. We start with the generalized Hubbard Hamiltonian on a periodic lattice with N sites:

$$H = H_0 + H_1, \quad (1)$$

$$H_0 = \sum_{\vec{r}, \vec{r}', \sigma} t(\vec{r} - \vec{r}') c_{\sigma}^{\dagger}(\vec{r}') c_{\sigma}(\vec{r}), \quad (2)$$

$$H_1 = \sum_{\vec{r}, \vec{r}'} [g_S(\vec{r} - \vec{r}') S^{\dagger}(\vec{r}, \vec{r}') S(\vec{r}, \vec{r}') + g_T(\vec{r} - \vec{r}') \sum_{\mu} T_{\mu}^{\dagger}(\vec{r}, \vec{r}') T_{\mu}(\vec{r}, \vec{r}')], \quad (3)$$

where $\vec{r}, \vec{r}'$ denote the positions of electrons and S, T are singlet and triplet pairing operators:

$$S(\vec{r}, \vec{r}') = \frac{c_{\uparrow}(\vec{r}) c_{\downarrow}(\vec{r}') + c_{\uparrow}(\vec{r}') c_{\downarrow}(\vec{r})}{2}, \quad (4)$$

$$T_0(\vec{r}, \vec{r}') = \frac{c_{\uparrow}(\vec{r}) c_{\downarrow}(\vec{r}') - c_{\uparrow}(\vec{r}') c_{\downarrow}(\vec{r})}{2}, \quad (5)$$

$$T_+(\vec{r}, \vec{r}') = \frac{c_{\uparrow}(\vec{r}) c_{\uparrow}(\vec{r}')}{\sqrt{2}}, \quad (6)$$

$$T_-(\vec{r}, \vec{r}') = \frac{c_{\downarrow}(\vec{r}) c_{\downarrow}(\vec{r}')}{\sqrt{2}}. \quad (7)$$

In the standard Hubbard model notation $g_S(R_i, R_i) = U$, $g_S(R_i, R_j) = W_{ij}$ and $g_T(R_i, R_j) = W_{ij}$. The inclusion of antiferromagnetic exchange $\sum_{ij} J_{ij} \cdot \vec{S}_i \cdot \vec{S}_j$, $J_{ij} > 0$ amounts to change $g_S(R_i, R_j) = W_{ij} - 3J_{ij}/2$, $g_T(R_i, R_j) = W_{ij} + J_{ij}/2$ and triplet pairing can be suppressed. From now on we will consider the singlet pairing only.

A convenient basis set in the Hilbert space of two fermions consists of states $|\vec{P}, \vec{r}, \sigma_1, \sigma_2\rangle$ with total Bloch momentum $\vec{P}$ and relative separation $\vec{r}$. In relative coordinates in the reciprocal space the eigenvectors of the kinetic part of the Hamiltonian (1) are the states:

$$|\vec{P}, \vec{p}, \sigma_1, \sigma_2\rangle = c_{(\vec{P}/2) - \vec{p}, \sigma_1}^{\dagger} c_{(\vec{P}/2) + \vec{p}, \sigma_2}^{\dagger} |0\rangle, \quad (8)$$

with the eigenvalues:

$$E_{\vec{P}\vec{p}} = \epsilon_{\vec{P}/2 - \vec{p}} + \epsilon_{\vec{P}/2 + \vec{p}}, \quad (9)$$

where

$$\epsilon_{\vec{p}} = -2t_1(\cos(p_x\delta) + \cos(p_y\delta)) - 4t_2 \cos(p_x\delta) * \cos(p_y\delta). \quad (10)$$

where δ is a lattice constant. We also define

$$\frac{1}{\sqrt{N}}\psi(\vec{r}|\vec{p}) = \langle \vec{P}, \vec{r}, \sigma_1, \sigma_2 | \vec{P}, \vec{p}, \sigma_1, \sigma_2 \rangle = e^{i\vec{p}\cdot\vec{r}}, \quad (11)$$

$$\frac{1}{\sqrt{N}}\psi(\vec{r}) = \langle \vec{P}, \vec{r}, \sigma_1, \sigma_2 | \vec{P}, \psi, \sigma_1, \sigma_2 \rangle, \quad (12)$$

where $\psi(\vec{r})$ is a wave function in the relative position space, a result of projection of any two-fermion state on a state with definite relative separation $\vec{r}$ and total Bloch momentum $\vec{P}$. To solve the Schrödinger equation

$$(H_0 + H_1)|\vec{P}, \psi \rangle = E|\vec{P}, \psi \rangle, \quad (13)$$

where H_0 is the kinetic part of the Hamiltonian (1), we introduce:

$$|\vec{P}, \psi \rangle = \sum_{\vec{p}} F(\vec{p})|\vec{P}, \vec{p} \rangle, \quad (14)$$

which yields an integral equation for coefficients $F(p)$:

$$\begin{aligned} (E - E_{\vec{P}\vec{p}})F(\vec{p}) &= \sum_{\vec{q}} F(\vec{q}) \langle \vec{P}\vec{p} | H_1 | \vec{P}\vec{q} \rangle = \\ &= \frac{1}{N} \sum_{\vec{r}} \psi^*(\vec{r}|\vec{p})g(\vec{r}) \sum_{\vec{q}} F(\vec{q})\psi(\vec{r}|\vec{q}). \end{aligned} \quad (15)$$

Using the above formula for $F(p)$ and definition: $\psi(\vec{r}) = \sum_{\vec{p}} F(\vec{p})\psi(\vec{r}|\vec{p})$, one obtains the final equation for the wave function $\psi(\vec{r})$:

$$\psi(\vec{r}) = \sum_{\vec{r}'} G(E, \vec{p}, \vec{r}, \vec{r}')g(\vec{r}')\psi(\vec{r}'), \quad (17)$$

where:

$$G(E, \vec{P}, \vec{r}, \vec{r}') = \frac{1}{N} \sum_{\vec{q}} \frac{\psi(\vec{r}|\vec{q})\psi^*(\vec{r}'|\vec{q})}{E - E_{\vec{P}\vec{q}}}, \quad (18)$$

is the Green function.

For the sites where interaction g is present, Eq. (17) can be cast into the form:

$$[1 - \mathcal{G}(E, \vec{P})g]\psi = 0, \quad (19)$$

where ψ is a $n \times 1$ matrix with $\psi_j = \psi(R_j)$, $\mathcal{G}(E, \vec{P})$ is a $n \times n$ matrix with $\mathcal{G}_{ij}(E, \vec{P}) = G(E, \vec{P}, R_i, R_j)$ and g is a diagonal $n \times n$ matrix with $g_{ii} = g(R_i)$ where $g(R_i) \neq 0$ only for sites $\vec{r} = 0, \pm R_1, \dots, \pm R_{n-1}$. The energy eigenvalues are calculated from the determinant:

$$\det[1 - \mathcal{G}(E, \vec{P})g] = 0. \quad (20)$$

To get the wave function for lattice sites outside described range we have to use Eq. (17).

B. Final equations

The matrix element in the reciprocal space is given as:

$$N \langle \vec{P} \vec{p} | H_1 | \vec{P} \vec{q} \rangle = g_0 + g_1 \gamma_{\vec{p}-\vec{q}}^{(1)} + g_2 \gamma_{\vec{p}-\vec{q}}^{(2)}, \quad (21)$$

where: $\gamma_{\vec{p}}^{(1)} = 2[\cos(p_x\delta) + \cos(p_y\delta)]$, $\gamma_{\vec{p}}^{(2)} = 4 \cos(p_x\delta) \cos(p_y\delta)$, $g_0 = U$ is the on-site interaction, $g_1 = W_1$ and $g_2 = W_2$ denote intersite interactions between nn and nnn, respectively. A separation of the matrix element (21) into parts depending exclusively on $\vec{p}$ and $\vec{q}$ is done by using five components $\psi_n(\vec{p})$, transforming according to irreducible representations of the symmetry group of the $d = 2$ lattice C_{4v} (given in the third column):

$$\begin{aligned} \psi_0 &= 1, & (s\text{-wave}) & A_1 \\ \psi_1(\vec{p}) &= \cos(p_x\delta) + \cos(p_y\delta), & (\text{ext. } s^*\text{-wave}) & A_1 \\ \psi_2(\vec{p}) &= \cos(p_x\delta) - \cos(p_y\delta), & (d_{x^2-y^2}\text{-wave}) & B_1 \\ \psi_3(\vec{p}) &= 2\cos(p_x\delta) * \cos(p_y\delta), & (s_{xy}^*\text{-wave}) & A_1 \\ \psi_4(\vec{p}) &= 2\sin(p_x\delta) * \sin(p_y\delta). & (d_{xy}\text{-wave}) & B_2 \end{aligned} \quad (22)$$

With such a form of the basis functions the Green's function is given by:

$$G_{nm}(E, \vec{P}) = \frac{1}{N} \sum_{\vec{p}} \frac{\psi_n(\vec{p}) \psi_m(\vec{p})}{E - E_{\vec{P}\vec{p}}}. \quad (23)$$

Above decomposition allows to write the following equation for $F(\vec{p})$ being the Fourier transform of $\psi(\vec{r})$:

$$F_m = \sum_{n \in \mathcal{R}} g_n G_{nm}(E, \vec{P}) F_n, \quad (24)$$

for each irreducible representation, where $F_m = (1/N) \sum_{\vec{p}} F(\vec{p}) \psi_m(\vec{p})$. Equation (20) for eigenvalues E takes the form shown below – for s^* -wave pairing (compare also [5,6]):

$$\det \begin{pmatrix} 1 - G_{00}U & -G_{01}W_1 & -G_{03}W_2 \\ -G_{01}U & 1 - G_{11}W_1 & -G_{13}W_2 \\ -G_{03}U & -G_{13}W_1 & 1 - G_{33}W_2 \end{pmatrix} = 0, \quad (25)$$

for $d_{x^2-y^2}$ -wave:

$$1 + |W_1|G_{22} = 0, \quad (26)$$

and for d_{xy} :

$$1 + |W_2|G_{44} = 0. \quad (27)$$

The above decomposition holds for arbitrary t_2 and $\vec{P} = 0$ or $t_2 = 0$ and $\vec{P}$ on the ΓM line as well as for any t_2 with $\vec{P}$ on the ΓM line and $W_2 = 0$. In general case one has to resort to Eq.(20).

Eq. (25) reads:

$$(1 - G_{00}U)(1 - G_{11}W_1)(1 - G_{33}W_2) - UW_1W_2(2G_{01}G_{13}G_{03} - G_{03}^2G_{11} - G_{13}^2G_{00} - G_{01}^2G_{33}) - G_{03}^2UW_2 - G_{13}^2W_1W_2 - G_{01}^2UW_1 = 0. \quad (28)$$

From Eq. (28) we can derive simpler cases [6]:

$$\begin{aligned} G_{11} &= -1/|W_1|, & \text{for } W_2 = 0 = U; \\ -G_{00}(1 + G_{11}|W_1|) + G_{01}^2|W_1| &= 0, & \text{for } W_2 = 0, U = \infty. \end{aligned} \quad (29)$$

The relative pair mobility which is defined as:

$$Z = \frac{2m_f}{m^*} \quad (30)$$

where m^* is an effective mass of a bound pair, and for $a \equiv t_2/t_1 \neq 0$, for two-dimensional square lattice $2m_f = \hbar^2/(t_1 + 2t_2)\delta^2$. Effective mass m^* can be obtained by expanding the denominator in Eq.(23). We take:

$$E - E_{\vec{P}\vec{P}} = 2\epsilon_0 - E_b - \omega_{\vec{P}} - \epsilon_{\vec{P}/2-\vec{P}} - \epsilon_{\vec{P}/2+\vec{P}}, \quad (31)$$

where E_b is the binding energy at $\vec{P} = 0$, $\omega_{\vec{P}}$ is the dispersion of the bound state and $\epsilon_{\vec{P}}$ is given by Eq. (10). In the long-wavelength limit on the ΓM line: $\omega_{\vec{P}} = DP^2$ where $D = \hbar^2\delta^2/2m^*$. The coefficient D is obtained by expanding $\epsilon_{\vec{P}/2\pm\vec{P}}$ into powers of $\vec{P}$, inverting the series and substituting resulting $G_{nm}(E, \vec{P})$ into appropriate Eqs (26 – 29). The final equations for pair mobilities in the simplest cases are:

$$Z = \frac{1}{1+2a} * \frac{A_{nn}}{B_{nn}}, \quad (32)$$

where $n = 1$ for s^* -wave pairing with $U = 0$ and $W_2 = 0$; $n = 2$ for $d_{x^2-y^2}$ and $n = 4$ for d_{xy} pairing with $a = 0$, respectively. We have used denotations:

$$A_{nm} = \frac{1}{2}B_{nm1} + aB_{nm3}, \quad (33)$$

$$B_{nms} = \frac{1}{N} \sum_p \frac{\psi_n(p)\psi_m(p)\psi_s(p)}{(2\epsilon_0 - E_b - 2\epsilon_p)^2}, \quad (34)$$

$$B_{nm} = B_{nm0}. \quad (35)$$

Mobilities in other cases have more complicated forms.

III. RESULTS

In Figs (1) - (3) we have plotted the binding energies and mobilities vs $|W_1/8t_1|$ for extended- s pairing (denoted as s^*) and for $d_{x^2-y^2}$ -wave pairing (in short d), for nnn hopping with parameter $a = 0$, $a = -0.2$ and $a = -0.45$. The last two values roughly correspond to the values of the parameter a , suggested by the band structure calculations in $La_{2-x}Sr_xCuO_4$ ($a \simeq -0.25$) and $YBa_2Cu_3O_{7-x}$ ($a \simeq -0.45$) [4].

With only the nn hopping taken into account (i.e. $a = 0$) for $U = 0$ infinitesimally small value of $|W_1|$ can create a bound state (of the s^* type) – there is no critical value. For finite U or

W_2 , including the case of the infinite on-site repulsion, $|W_1|$ has to reach critical value to create such a bound state ($|W_{1c}|/8t_1 = 0.25$ for s^* -wave for $U = \infty$ for $a = 0$). The d -wave pairing does not depend on U , and also a critical value of $|W_{1c}|/8t_1 = 0.915$ (or $|W_{2c}|/8t_1 = 0.8268$ in the case of d_{xy}) has to be reached to form a pair of the d type. In this case ($a = 0$), the binding energies of d type are smaller than the s -wave binding energies in the whole range of displayed parameters. The mobility of pairs is smaller than 1 (i.e. the effective mass of a pair is larger than the mass of its constituent fermions) and decreases with increasing intersite attraction. Increasing $|W_1|$ makes the binding stronger, but at the same time, the pair movement more difficult. The mobility increases with decreasing $|W_1|$ for $a = 0$, and is always smaller for d -wave than s -wave. Let us note, that the mobility of the s^* -pairs for $U = \infty$ becomes larger than the mobility of the s^* -pairs for $U = 0$ near the critical value of W_1 . It is so, despite the fact, that the binding energies for $U = \infty$ are smaller than in the $U = 0$ case. It is also of interest, that both mobility and binding energies of the s^* -pairs for $U = \infty = W_2$ resemble the respective quantities of the d -wave pairing. Differences appear near the critical value, which is slightly smaller in the s^* case, with s^* mobility there about twice as large as in the d case, but they diminish very quickly with increasing $|W_1|$.

The situation changes rapidly with increasing t_2 (which is taken with the opposite sign than t_1). The binding energy of d -wave pairs grows and can become larger than that of s -wave pairs for large enough $|W_1|$. The same happens for the mobilities. For the d -wave, the mobility grows faster than s -wave and for large enough $|W_1|$ (although not the same as for pair binding energies) the mobility of d -pairs exceeds that of s -pairs. Starting from $|a| \approx 0.3$ the pair mobilities can become greater than 1 and even strongly bound pair can easily move without breaking its bond. For $|W_1| \rightarrow \infty$, $Z \rightarrow \pm|a|/(1 + 2a)$ with $+(-)$ for d (s^*) -wave pairs, respectively [1].

The increase of pair mobilities with the parameter $|a|$ is much more abrupt for d -wave pairing than for s -wave, so at the value $a = -0.45$ the maximum of d -pairs mobility is around 6 while that of s -pairs around 4, and the mobility for s -wave is smaller than for d -wave in the whole range of displayed W_1 values (Fig. 3).

With growing $|a|$ a new feature develops: a maximum appears in the mobility curves. The mobility generally increases with a and decreases with $|W_1|$ but is not the largest for the critical value of W_1 . For s^* -wave pairing with $U = 0$ the mobility for $W_1 = 0$ is always equal to the mass of two free fermions, i.e. 1 in our units. For small binding energies, the mobility increases with $|W_1|$ and diminishes only later, for still larger $|W_1|$, which creates a maximum. This is a consequence of the saddle points located at $(0, \pi)$ and $(\pi, 0)$ in the reciprocal space. The dispersion curves are anomalously flat in that region (as can be seen in Fig. 5), particles move slower and the probability of pairing increases. The singularity is only "felt" by the shallow states, which results in a maximum for small $|W_1|$.

We note that for large enough $|W_1|$ the mobility of s^* bound pairs becomes negative, which is connected to the fact that the minimum of BS energy moves from $k = 0$ towards $k = \pi$.

In Figs (4) and (5) we show the bound state dispersion curves across the Brillouin zone for $W_2 = 0$. The BS energies of d - and s^* - pairing are the same at the zone boundary. At the Γ point d -wave BS energy is larger or smaller than s -wave BS energy, depending on a and $|W_1|$. The d -wave BS energies can be larger than s -wave ones in a part of the B. z. and smaller in another part of the B. z. and the possibility of mixed $s^* - d$ state emerges.

In Fig. (5) we plotted the dispersion curves along the lines $\Gamma - M - X - \Gamma$ for $a = -0.45$. We observe a mixing of s^* and d wave states and well developed dispersion for deep bound

states. Calculations for small binding energies show, however, that shallow bound states may exist only in parts of the B.z. We were unable to find bound states in the domain of real energies near the M point for small $|W_1|$ (both in the case of s^* - and d -wave pairing). There is a possibility that BS enter the scattering continuum and turn into resonance states. The problem of the resonance states is left for further study.

Fig. (6) shows the ground state diagram for the shallow bound states. The nnn interaction W_2 was assumed to be positive, i.e. we disregarded d_{xy} pairing. The resulting curves show, that for nn hopping s^* -wave pairing prevails even for the infinite nnn repulsion. The inclusion of t_2 together with the on-site repulsion act in favour of d -wave pairing. For a given U , a finite W_2 is needed to get the ground state of d -wave symmetry.

Finally, let us point out that our results for existence of two-body BS in the s -wave channel are directly related to the stability of s -wave superconductivity on 2D lattice in a dilute limit [7].

IV. CONCLUSIONS

We have examined two-electron bound states in an extended Hubbard model with nnn hopping and nnn interaction. The analysis shows that t_2 affects kinetic energy of pairs in a considerable way. This second hopping, with opposite sign to t_1 , enhances d -wave pairing more than s^* -wave. The nnn hopping increases the relative pair mobility, which can become greater than that of free fermions (and a possibility of long-lived highly mobile bound pairs arises), in agreement with [1]. The increase of $d_{x^2-y^2}$ -wave pair mobility is much larger than the respective one of the s^* -wave. The nnn interaction influences the d -wave pairing only of the d_{xy} type. We have also exemplified the possibility of existence of a $s^* - d_{x^2-y^2}$ mixed state. We have also pointed out that for large t_2 shallow bound states may exist only in certain regions of B.z., in contrast to the deep bound states which can occur in the whole B.z., for strong enough intersite attraction.
